---

5     **Abstract**

*MicroxanoX* is an R package to simulate a three functional group ecosystem (cyanobacteria, phototrophic sulfur bacteria, and sulfate-reducing bacteria) with four chemical substrates (phosphorus, oxygen, reduced sulfur, and oxidized sulfur) using a set of ordinary differential equations. Simulations can be run individually or over a parameter range. The model can be implemented with different numbers of species per functional group. The package is constructed in such a way that the results contain the input parameter used, so that a saved results can be loaded again and the simulation be repeated. Furthermore, the package framework and code should serve as a useful starting point for making simulation models of other types of ecosystems.

## 11 2. Motivation and significance

12 Mathematical models play a key role in the development of ecosystem models  
 13 and in increasing the understanding of how and why ecosystems change when the  
 14 environment changes [1, 3, 17]. They are also important for developing hypotheses

15 to test in empirical studies. One area of ecology in which models have been  
16 influential is the understanding of ecosystem responses to gradual change in an  
17 environmental driver [12]. An environmental driver is an environmental condition  
18 that affects an ecosystem, but which is not itself affected by the ecosystem. An  
19 example driver would be the amount of nutrients entering a lake from run-off  
20 from surrounding agricultural land.

21 It is conceivable that an ecosystem state, such as the total biomass of a  
22 particular type of bacteria, may remain unchanged when an environmental driver  
23 changes. It is also possible that the ecosystem state changes gradually. It is  
24 also possible that the ecosystem state changes abruptly to a new state that is  
25 difficult to recover from [12]. This possibility for abrupt, perhaps catastrophic  
26 changes, which are difficult to reverse, causes considerable concern [4, 9, 16].

27 An example where a gradual change of an environmental variable causes an  
28 abrupt change in the system is the switch from an aerobic (oxygen is available for  
29 metabolism) to an anaerobic (oxygen generally unavailable) state in a microbial  
30 ecosystem. This system has been investigated by Bush et al. [2] in a simulation  
31 study of a mathematical model. Three types of microbes occur in the model:  
32 cyanobacteria (CB) dominating the oxic state, and two types of sulfur bacteria  
33 that dominate the anoxic state (sulfate reducing bacteria (SB) and phototrophic  
34 sulfur bacteria (PB)). The model shows that gradual change in the rate at which  
35 oxygen can diffuse into the ecosystem (termed oxygen diffusivity) could cause  
36 catastrophic changes in the ecosystem state that would be difficult to reverse.

37 One feature of the study by Bush et al. [2] was limited biodiversity. Specifically,  
38 there was no biodiversity within each of the three types (i.e., functional groups)  
39 of bacteria. This leaves the question of if and how biodiversity within these  
40 functional groups might affect the ecosystem response to environmental change.  
41 This limitation is not specific to the study of Bush et al. [2]. There are few if any  
42 studies of the effects of biodiversity on abrupt transitions between ecosystem  
43 states.

44 We decided to fill this research gap by making a simulation study of how  
45 within functional group biodiversity affects ecosystem responses to environmental  
46 change Limberger et al. [8], and to base our work on the work and model of  
47 Bush et al. [2]. With this goal in mind, we developed the `microxanox` package  
48 [7]. The first stage of development was to write code from scratch (as there was  
49 no available code to start from) and to confirm that this new implementation  
50 would reproduce the previously published results. The resulting reproduction is  
51 available as one of the package vignettes: [vignette Partial reproduction of Bush](#)  
52 [et al.](#)

53 The second stage was to add functionality that would be necessary to answer  
54 our research question. Most importantly, we made it possible to have multiple  
55 species of bacteria within each of the three functional groups, for the multiple  
56 species to differ in their characteristics, and to vary the number of species and  
57 amount of variability among them. We also added functionality that allowed:  
58 temporally varying environmental conditions, the addition of random noise to  
59 state variables, and immigration. In addition to the model itself, the package  
60 includes some functions to analyse the results and visualize these to provide a

61 starting point for customized visualizations based on own requirements. The  
62 basic and additional functionality is described in the package [User Guide](#).

### 63 3. Software description

64 The *microxanox* package is for simulating a three functional group system  
65 (*CB*: cyanobacteria, *PB*: phototrophic sulfur bacteria, and *SB*: sulfate-reducing  
66 bacteria) with four chemical substrates (*P*: phosphorus, *O*: oxygen, *SR*: reduced  
67 sulfur, *SO*: oxidized sulfur). It includes feedback between organisms and biogeo-  
68 chemical processes and is based on Bush et al. [2] (See Bush et al. [2] for a detailed  
69 discussion of the model). At the core of the simulations is a set of ordinary  
70 differential equations (specified in the function `bushplus_dynamic_model()`,  
71 though this function need not be directly called). There are functions for run-  
72 ning individual simulations and a set of simulations across, for example, a range  
73 of environmental conditions.

74 To make the simulation run with multiple species per functional group, we  
75 expressed different species' characteristics in the elements of vectors and matrices.  
76 We also coded the ordinary differential equations **to include the vectors and**  
77 **matrices and used matrix mathematics**. In this way, we made it possible to  
78 run simulations with different numbers of species without having to change the  
79 underlying code.

80 The package functions and code have a modular structure so that new  
81 functionality can be easily added. E.g., temporally defined events of any type  
82 could be specified. Further, all parameter values required to run a simulation  
83 are stored in one object. Lastly, the general structure of the code should make it  
84 straightforward to adapt the model to other similar systems (described in more  
85 detail in the Impact section).

#### 86 3.1. Software architecture

87 The framework used when writing this package aimed to maximise simplicity  
88 for the user and to make it straightforward to reproduce results (see the supple-  
89 ment [10] to Limberger et al. [8] for an example of how this is used). As such, all  
90 the parameters needed to run a simulation or a set of simulations are contained  
91 in a single object (which can easily be created using included functions). This  
92 parameter object is given to a function that runs the simulations and returns the  
93 results. The returned results object is identical to the parameter object but with  
94 an additional slot named `results`, which contains the simulation results. Thus  
95 the returned results object contains the simulation conditions (parameters) as  
96 well as the results, and can be used to run the simulation again. This promotes  
97 reproducibility and makes incremental changes of individual parameters with a  
98 consecutive re-running of the simulations straightforward.

99 In the following sections we describe how to use the package to run one  
100 simulation and to find final states across an environmental gradient.

Figure 1: Typical flow of a simulation. Dark Grey boxes: commands necessary for simulation; Light Grey: Saving of parameter and results; Lightest Grey: Different non specified commands.

### 101 3.2. Running one simulation

102 A typical simulation would look as shown in Figure 1.

103 A simulation is run using the `run_simulation()` function. In this function,  
104 the ODEs are solved using the function `ode()` in the package *deSolve* package [14].  
105 The `run_simulation()` function needs only one argument - an object as created  
106 by the function `new_runsim_parameter()`. The parameter object returned by  
107 `new_runsim_parameter()` contains, among other things, the `strain_parameter`  
108 object, which can be created by the function `new_strain_parameter()`. For  
109 a detailed description of the parameter objects, their meaning and how they  
110 are created and have values set and changed, please see the *User Guide* which  
111 accompanies the package or is available at [User Guide](#).

112 After the parameter object has been defined, it can be used in the `run_simulation()`  
113 function. The function returns an object identical to the parameter object, ex-  
114 cept of an `additional slot` containing the results. This design produces a fully  
115 reproducible object as it can be used as a parameter object to be fed back into the  
116 `run_simulation()` function to rerun the simulation again from the parameter  
117 used to generate the results before.

### 118 3.3. Examining ecosystem responses to environmental change

119 One approach to finding how the ecosystem responds to environmental driver  
120 change is to examine the relationship between the environmental driver value and  
121 the numerical value of a system's state. The first component of this approach is  
122 to run the simulation for a long time and record the final state (i.e., the state of  
123 the system at the end of a simulation). When one does this across a range of  
124 environmental conditions, one can discover how the final state of the system  
125 changes with the environmental conditions. The package contains functionality  
126 for finding final states that correspond to values of one environmental driver,  
127 namely the value of oxygen diffusivity. In terms of non-linear systems analysis,  
128 this would be termed a *parameteric sensitivity analysis* being conducted by  
129 running an open loop of the dynamic system under a set of initial conditions  
130 and a subset of parameter values (here oxygen diffusivity).

131 When one wishes to be able to make conclusions about how the *steady state*  
132 (or an equilibrium point) of the system is affected by the environmental driver,  
133 it is very important to note that the *final state* (provided by the simulation)  
134 is not guaranteed to be a *steady state*. The software does not provide the user  
135 with a steady state. In order to somewhat safely assume that the final state is a  
136 steady state, the user must ensure that the simulation is run for sufficiently long  
137 time for any transient dynamics to disappear, and must also check the type of  
138 long-term dynamics occurring. In the results presented here, and in the paper  
139 Limberger et al. [8], this was performed by visual inspection, and by checking  
140 the sensitivity of conclusions to the length of the simulation. Furthermore, the  
141 package does not include methods for a formal analysis of the stability of the  
142 system and users should take care to assess if steady states are unique.

143 Two numerical strategies for finding final states and their sensitivity to  
144 parameters are implemented. Two strategies are implemented in order to allow

145 users to compare of their results. The first method runs a independent simulation  
146 for each combination of initial conditions and oxygen diffusivity (we term this  
147 the *Replication method*). This is the method used in the Bush et al. [2] study  
148 and was used to obtain the results in figures 3 and 4 of that article.

149 The second method runs two simulations, one with step-wise and slowly  
150 temporally *increasing* oxygen diffusivity, and the other with step-wise and slowly  
151 *decreasing* oxygen diffusivity. (Put another way, to explore the sensitivity of  
152 final states of the dynamic model under oxygen diffusivity variation, subset  
153 values of this parameter are numerically evaluated. Two value vectors of oxygen  
154 diffusivity are presented step-wise, gradually increasing and decreasing.) During  
155 this temporal environmental change, the state of the system is recorded just  
156 before change to a new oxygen diffusivity (we term this the *Temporal method*).

157 An potentially important difference between the two methods is in the system  
158 state when a new value of oxygen diffusivity is set. In the replication method,  
159 the system state when a new value of oxygen diffusivity is set is always the same.  
160 Whereas in the temporal method, the system state when a new value of oxygen  
161 diffusivity is set is the final state of the system for the previously set value of  
162 oxygen diffusivity. Since some modellers prefer one approach and others another,  
163 we decided to implement both.

164 The replication method is implemented in the function `run_replication_ssfind()`  
165 which takes a parameter object as returned by the function `new_replication_ssfind_parameter()`  
166 and the number of cores for multithreading the simulation. As the multithreading  
167 uses the package function `mclapply()` from the package `parallel` [11], the mul-  
168 titheading only works on Linux and Mac. It is planned to move to `parLapply()`  
169 [11] in a future release.

170 The temporal method is implemented in the function `run_temporal_ssfind()`,  
171 which takes a parameter object as created by the function `new_temporal_ssfind_parameter()`.  
172 It is planned for a later release, to run these two simulations in parallel.

173 For a more detailed walk-through of these two approaches and explanation  
174 please see the [User Guide](#).

### 175 3.4. Analysing and visualising results

176 From the results returned, summary measures about how the ecosystem  
177 final states changes with environmental change can be extracted. The function  
178 `get_stability_measures()` returns quantities such as the amount of environ-  
179 mental change required for the system to abruptly change to a different state.

180 The function `plot_dynamics()` plots a single simulation run, as returned  
181 from the `run_simulation()` function. This function is only provided as a  
182 convenience function to provide a way to easily see the results of a simulation  
183 run. An example plot resulting from this function is shown in Figure 2.

## 184 4. Impact

185 The open source implementation and extension of the model used in Bush  
186 et al. [2] provides the means of reproducing the results published while at the

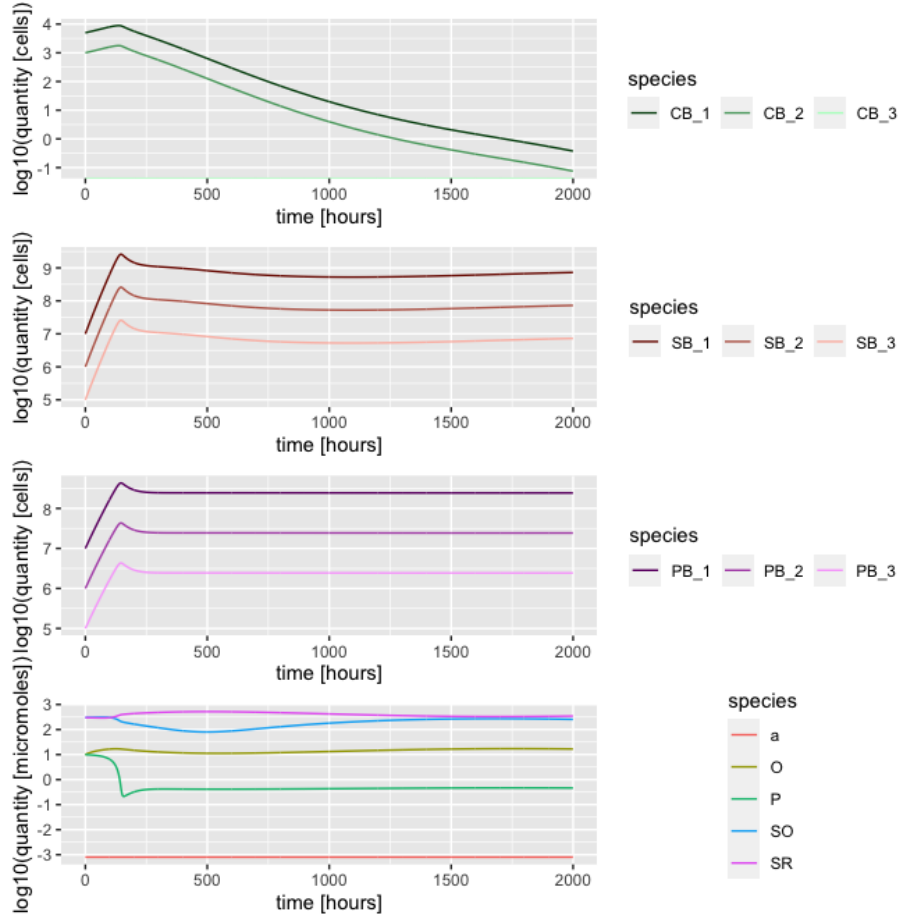

Figure 2: Results of a simulation run shown using the function `plot_dynamics()`. In this case, there were three strains per functional group, though strains within functional groups had identical properties in this example. CB\_1 = cyanobacteria strain 1; SB\_1 = sulfur reducing bacteria stain 1; PB\_1 = phototrophic sulfur bacteria strain 1.

187 same time provides the means of making unique, innovative, and important  
188 investigations of how ecosystems change as the environmental changes, and how  
189 biodiversity may modulate this.

190 The design of the package code and functionality is with reproducibility in  
191 mind (for other example of reproducibility directed software, see e.g. Correndo  
192 et al. [5], Spillner et al. [15] or Fox et al. [6]): the combination of all parameters  
193 being in a single parameter object and the return of the simulation as a result  
194 object which inherits from the parameter object, provides a relatively easy-to-use  
195 framework to implement reproducible experiments.

196 Here we evidence the impact of the *microxanox* package by describing three  
197 use-cases and then by describing how the package can be a starting point for  
198 models of other ecosystems. The first two use cases are described in detail  
199 (including the code for reproducing them) in the [User Guide](#) and the *Partial*  
200 *Reproduction* vignettes. The third is taken from Limberger et al. [8] and Petchey  
201 et al. [10].

#### 202 4.1. Use case 1: Regime shifts during temporal environmental change

203 The study of Bush et al. [2] includes simulations of the effect of oxygen  
204 diffusivity (an environmental driver, in the sense that it affects the ecosystem but  
205 is not affected by it) on the ecosystem state (oxic or anoxic). The *microxanox*  
206 package contains functionality to make a specific temporal pattern of change  
207 in the oxygen diffusivity. As well as allowing individual simulations during  
208 which oxygen diffusivity varies, this functionality forms the basis of the temporal  
209 method for finding final states.

210 An example of this functionality is given in the *Partial Reproduction* vignette,  
211 which we briefly describe and show here (Figure 3). The example is composed of  
212 a single simulation, at the beginning of which the system is in the oxic state with  
213 high abundance of cyanobacteria. Oxygen diffusivity is then slowly decreased  
214 and eventually, around hour 30'000 the system switches to the anoxic state, with  
215 high abundance of both sulfur bacteria types. The oxygen diffusivity is then  
216 increased and at around hour 38'000 the system abruptly switches back to the  
217 oxic state.

218 Also visible in the results are thick lines showing abundances of bacteria  
219 when abundances are low. This is due to the implementation of a function that  
220 at regular intervals, increases the abundance to a preset level. This prevents  
221 abundances reducing to very small numbers. The function that implements this  
222 increase abundance can also be made to add a certain abundance to each strain  
223 at regular intervals, thus simulating immigration in to the system.

#### 224 4.2. Use case 2: The extent of hysteresis depends on community composition

225 The package contains a function to extract summary features of ecosystem  
226 responses to environmental change, such as the amount of hysteresis displayed by  
227 the ecosystem. Hysteresis is a key feature of ecosystem responses to environmental  
228 change, because it is related to how difficult it can be to reverse the effects of  
229 environmental change [12]. The amount of hysteresis is measured as the extent

Figure 3: The temporal dynamics of the ecosystem model when an environmental condition (here parameter  $a$ , the oxygen diffusivity) changes. Plot of the final states of the simulation runs under different oxygen diffusivity. In this simulation there is only one strain in each functional group. CB extunderscore1 = cyanobacteria strain 1; SB extunderscore1 = sulfur reducing bacteria strain 1; PB = phototrophic sulfur bacteria strain 1. Here we show a figure adapted from the output of the `plot_dynamics()` function.

Figure 4: The amount of hysteresis depends on the combination of types of organisms present. The model is entirely deterministic, hence there are no error bars.

of the environmental condition (here oxygen diffusivity) for which there were two distinct final states. I.e., it is the extent of the environmental conditions for which historical conditions play an important role in determining the current system state.

Using the package to calculate the extent of hysteresis involves setting ecosystem and simulation parameters, including parameters for the finding of final states across an environmental gradient, running the final state finding function, and analysing the results with the function that calculates extent of hysteresis. The code for this is provided in the [User Guide](#).

The results show that the amount of hysteresis depends greatly on the combinations of organisms present (Figure 4). For example, with only the CB (cyanobacteria) present, there was no hysteresis. In contrast, the presence of both CB and SB (sulfate reducing bacteria) led to a large amount of hysteresis. (These results are also given in the *Partial Reproduction* vignette.)

#### 4.3. Use case 3: Effects of functional diversity on regime shifts

As discussed in the Introduction section, the package was motivated by the question of how biodiversity influences ecosystem responses to environmental change. Extensive results concerning this question are given in a separate publication Limberger et al. [8]. Here we describe one of the results, which is that having biodiversity in a functional group can allow state changes to occur that otherwise would not have, i.e. biodiversity can qualitatively change the state of the ecosystem.

Biodiversity was added to the functional groups using the `new_strain_parameter()` function to create a parameter set with multiple species per functional group (albeit all with identical features) and then to add variability among the species by calling the `add_strain_var()` function. This function takes an already existing parameter set and adds the specified amount of variation. The new parameter object is then used as before.

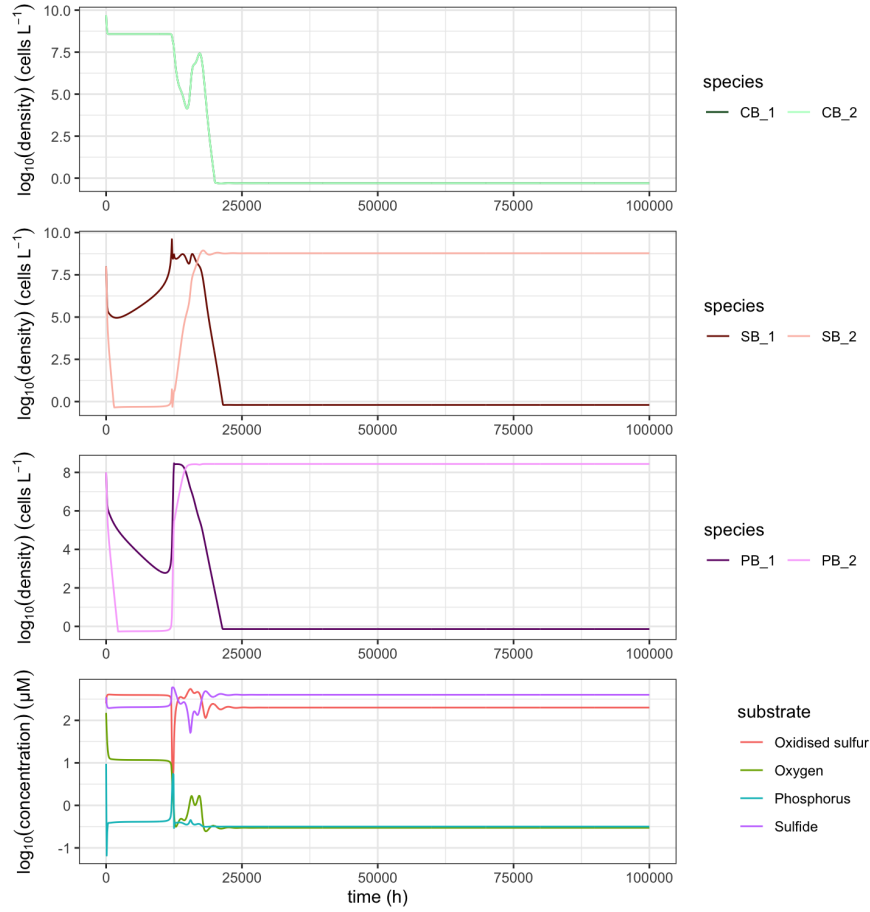

Figure 5: The dynamics of the ecosystem when there are two species in each functional group, and some variation (diversity) in species parameters.

Figure 5 shows a simulation with two species (strains) in each of the three functional groups. The ecosystem starts in the oxic state, though with relatively high abundance of each functional group. The strain of SB that is more tolerant to oxygen (SB\_1) initially decreases in abundance, but then increases, and the other (SB\_2) strain then becomes abundance and SB\_1 declines. Furthermore, the cyanobacteria crash in abundance, and the system switches to the anoxic state. In contrast, if there are two identical strains with tolerance half way between those in Figure 5 the ecosystem remains in the oxic state.

#### 4.4. Adapting for other ecosystems and organisms

We anticipate that the package can be a useful starting point for investigating models of other types of ecosystem and how biodiversity in them affects responses

269 to environmental change. The overall framework of the package, the purpose  
270 of each function, and the objects used for storing parameters and results could  
271 be retained. E.g., all such models would have parameters that differ among  
272 species and need to be described in an object, and studies will often need to run  
273 simulations and sets of simulations across environmental conditions.

274 Researchers wanting to model a new ecosystem do not, therefore, have to  
275 start from scratch. This will relieve researchers from needing to make software  
276 design decisions, and rather focus on appropriately representing their ecosystem  
277 and finding the results that interest them. Nevertheless, adaptation of the code  
278 in the package will require a person / persons that can take a conceptual model of  
279 an ecosystem and then represent that in terms of parameters and rate equations,  
280 and a person or persons relatively proficient in R programming.

## 281 5. Conclusions

282 The *microxanoz* R package allows the simulation, visualisation, and analysis  
283 of a model of a microbial ecosystem while allowing variation in the amount of  
284 diversity present in each of the functional groups of organisms present. It has  
285 been used for the research described in another paper that provides one of the  
286 first investigations of the effects of diversity on ecosystem resilience Limberger  
287 et al. [8]. In that paper, we show that diversity can have large and important  
288 effects on ecosystem responses, highlighting the need for models such as ours,  
289 with which one can easily manipulate the amount of biodiversity. The *microxanoz*  
290 package has also been used to reproduce the results of the paper that inspired  
291 the package development [2].

292 The package greatly lowers the amount of work required in further investi-  
293 gations of the specific ecosystem modelled. There has, for example, been quite  
294 limited investigation of how biodiversity influences the short-term responses of  
295 the modelled ecosystem to environmental change. Likewise, the package could be  
296 used to power an investigation of the effects of biodiversity on the usefulness of  
297 early warning signals of abrupt ecosystem change [13]. In addition this package  
298 could be used as a template for developing models of other types of ecosystems  
299 and organism. By doing so, other models can profit from the overall framework  
300 used, and the reproducibility aspects as well as the flexibility implemented.

## 301 6. Conflict of Interest

302 The authors declare no known conflicting or competing interests associated  
303 with this publication and there has been no significant financial support for this  
304 work that could have influenced its outcome.

## 305 7. Acknowledgements
